(57) **ABSTRACT**

Methods and systems for handling on an electronic device a secure message to be sent to a recipient. Data is accessed about a security key associated with the recipient. The received data is used to perform a validity check related to sending a secure message to the recipient. The validity check may uncover an issue that exists with sending a secure message to the recipient. A reason is determined for the validity check issue and is provided to the mobile device's user.

SYSTEM AND METHOD OF ACCESSING KEYS FOR SECURE MESSAGING

CROSS-REFERENCE TO RELATED APPLICATIONS

The present application is a continuation of U.S. patent application Ser. No. 13/586,703 entitled "System and Method of Accessing Keys for Secure Messaging," filed Aug. 15, 2012, which is a continuation of U.S. patent application Ser. No. 12/785,759 entitled "System and Method of Accessing Keys for Secure Messaging," filed May 24, 2010 and issued as U.S. Pat. No. 8,271,782 on Sep. 18, 2012, which is a continuation of U.S. patent application Ser. No. 10/817,070, entitled "System and Method of Accessing Keys for Secure Messaging," filed Apr. 2, 2004, which issued as U.S. Pat. No. 7,725,711 on May 25, 2010. The present application and the '703, '759, and '070 applications claim priority to and the benefit of U.S. provisional application Ser. No. 60/494,369, entitled "PUBLIC KEY ACCESS SCHEME FOR SECURE COMMUNICATIONS," filed Aug. 12, 2003. All of these are hereby incorporated into the present application by reference.

BACKGROUND

1. Technical Field

The present invention relates generally to the field of secure electronic messaging, and in particular to accessing keys for secure messaging.

2. Description of the Related Art

Known secure messaging software clients, such as e-mail software applications operating on desktop computer systems, provide limited information when an error is encountered in accessing a key (e.g., a public key) required for secure communications. Typically, only an indication that an error occurred is provided, without information on the nature of the error or possible corrective actions. Also, when such an error occurs, a user is often prevented from sending the message.

SUMMARY

In accordance with the teachings disclosed herein, methods and systems are provided for handling on an electronic device a secure message to be sent to a recipient. Data is accessed about a security key that is associated with the recipient. The data is used to perform a validity check related to sending a secure message to the recipient. The validity check may uncover an issue related to sending a secure message to the recipient. A reason is determined for the validity check issue and is provided to the electronic device's user.

As an example of a method to handle secure messages, a method may include receiving data about a security key associated with the recipient. The received data is used to perform a validity check with respect to using the message recipient's security key to send a secure message to the recipient. An issue may be determined to exist based upon the validity check. A reason for the issued is also determined and provided to the electronic device's user.

As an example of a system to handle secure messages, a system may include a secure message processing module for use with a messaging client to send electronic messages to recipients. The secure message processing module receives data about a security key associated with the recipient. The secure message processing module uses the received data to perform a validity check with respect to using the message recipient's security key to send a secure message to the recipient. An issue may exist based upon the validity check and a

2

reason is determined for the validity check issue. The secure message processing module provides the reason of the validity check issue to the electronic device's user.

BRIEF DESCRIPTION OF THE DRAWINGS

FIG. 1 is a block diagram of a messaging system.

FIG. 2 is a block diagram illustrating a secure e-mail message exchange in a messaging system.

FIG. 3 is a block diagram of a wireless mobile communication device implementing a public key access scheme.

FIGS. 4A-4C are flow charts illustrating a method of accessing public keys.

FIG. 5 is a block diagram of a wireless mobile communication device.

DETAILED DESCRIPTION

Approaches disclosed herein for handling secure messages on mobile devices may be used with many different types of security schemes and messaging systems. As an example, in a public key cryptography scheme, each user has a key pair including a public key that is distributed or available to other users and a private key that is known only to the user that is the "owner" of the key pair. For secure messaging operations based on public key cryptography, a user uses a private key to decrypt received encrypted messages and to sign messages to be sent. Public keys are used to encrypt messages to be sent and to verify digital signatures on received messages. Thus, access to public keys of other users is required for different secure messaging operations.

Secure messages may be signed with a digital signature, encrypted, or both signed and encrypted, and may also be processed in other ways by a message sender or intermediate system between a message sender and a messaging client which receives the secure message. For example, secure messages include messages that have been signed, encrypted and then signed, or signed and then encrypted, by a message sender according to variants of Secure Multipurpose Internet Mail Extensions (S/MIME). A secure message could similarly be encoded, compressed or otherwise processed either before or after being signed and/or encrypted.

A messaging client allows a system on which it operates to receive and possibly also send messages. Messaging clients operate on a computer system, a handheld device, or any other system or device with communications capabilities. Many messaging clients also have additional non-messaging functions.

FIG. 1 is a block diagram of a messaging system. The system 10 includes a Wide Area Network (WAN) 12, coupled to a computer system 14, a wireless network gateway 16, and a Local Area Network (LAN) 18 (e.g., a corporate LAN). The wireless network gateway 16 is also coupled to a wireless communication network 20, in which a wireless mobile communication device 22 ("mobile device") is configured to operate.

The computer system 14 is a desktop or laptop personal computer (PC), which is configured to communicate to the WAN 12, which is the Internet in most implementations. PCs, such as computer system 14, normally access the Internet through an Internet Service Provider (ISP), an Application Service Provider (ASP), or the like.

The corporate LAN 18 is a network-based messaging client. It is normally located behind a security firewall 24. Within the corporate LAN 18, a message server 26, operating on a computer behind the firewall 24, serves as the primary interface for the corporation to exchange messages both

within the LAN 18, and with other external messaging clients via the WAN 12. Two known message servers 26 are Microsoft™ Exchange server and Lotus Domino™ server. These servers 26 are often used in conjunction with Internet mail routers that route and deliver mail messages. A server such as the message server 26 also typically provides additional functionality, such as dynamic database storage for calendars, todo lists, task lists, e-mail, electronic documentation, etc.

The message server 26 provides messaging capabilities to the corporation's networked computer systems 28 coupled to the LAN 18. A typical LAN 18 includes multiple computer systems 28, each of which implements a messaging client, such as Microsoft Outlook™, Lotus Notes, etc. Within the LAN 18, messages are received by the message server 26, distributed to the appropriate mailboxes for user accounts addressed in the received message, and then accessed by a user through a computer system 28 operating as a messaging client.

The wireless gateway 16 provides an interface to a wireless network 20, through which messages are exchanged with a mobile device 22. Such functions as addressing of the mobile device 22, encoding or otherwise transforming messages for wireless transmission, and any other required interface functions are performed by the wireless gateway 16. Although the wireless gateway 16 operates with the single wireless network 20 in FIG. 1, wireless gateways may be configured to operate with more than one wireless network in alternative embodiments, in which case the wireless gateway may also determine a most likely network for locating a given mobile device user and may also track users as they roam between countries or networks.

Any computer system 14, 28 with access to the WAN 12 may exchange messages with a mobile device 22 through the wireless network gateway 16. Alternatively, private wireless network gateways, such as wireless Virtual Private Network (VPN) routers, could be implemented to provide a private interface to a wireless network. For example, a wireless VPN router implemented in the LAN 18 would provide a private interface from the LAN 18 to one or more mobile devices such as the mobile device 22 through the wireless network 20. Wireless VPN routers and other types of private interfaces to the mobile device 22 may effectively be extended to entities outside the LAN 18 by providing a message forwarding or redirection system that operates with the message server 26. Such a redirection system is disclosed in U.S. Pat. No. 6,219,694, which is hereby incorporated into this application by reference. In this type of redirection system, incoming messages received by the message server 26 and addressed to a user of a mobile device 22 are sent through the wireless network interface, either a wireless VPN router, wireless gateway 16 or other interface, to the wireless network 20 and to the user's mobile device 22. Another alternate interface to a user's mailbox on a message server 26 is a Wireless Application Protocol (WAP) gateway, through which a list of messages in a user's mailbox on the message server 26, and possibly each message or a portion of each message, could be sent to the mobile device 22.

Wireless networks such as the wireless network 20 normally deliver information to and from mobile devices via RE transmissions between base stations and the mobile devices. The wireless network 20 may, for example, be a data-centric wireless network, a voice-centric wireless network, or a dual-mode network that can support both voice and data communications over the same infrastructure. Known data-centric network include the Mobitex™ Radio Network ("Mobitex"), and the DataTAC™ Radio Network ("DataTAC"). Examples

of known voice-centric data networks include Personal Communication Systems (PCS) networks like Global System for Mobile Communications (GSM) and Time Division Multiple Access (TDMA) systems. Dual-mode wireless networks include Code Division Multiple Access (CDMA) networks, General Packet Radio Service (GPRS) networks, and so-called third-generation (3G) networks, such as Enhanced Data rates for Global Evolution (EDGE) and Universal Mobile Telecommunications Systems (UMTS), which are currently under development.

The mobile device 22 is a data communication device, a voice communication device, or a multiple-mode device capable of voice, data and other types of communications. An exemplary mobile device 22 is described in further detail below.

Perhaps the most common type of messaging currently in use is e-mail. In a standard e-mail system, an e-mail message is sent by an e-mail sender, possibly through a message server and/or a service provider system, and is then routed through the Internet, when necessary, to one or more message receivers. E-mail messages are normally sent in the clear and typically use Simple Mail Transfer Protocol (SMTP) headers and Multi-purpose Internet Mail Extensions (MIME) body parts to define the format of the e-mail message.

In recent years, secure messaging techniques have evolved to protect both the content and integrity of messages, such as e-mail messages. S/MIME and Pretty Good Privacy™ (PGP™) are two public key secure e-mail messaging protocols that provide for both encryption, to protect data content, and signing, which protects the integrity of a message and provides for sender authentication by a message receiver. In addition to utilizing digital signatures and possibly encryption, secure messages may also be encoded, compressed or otherwise processed.

FIG. 2 is a block diagram illustrating a secure e-mail message exchange in a messaging system. The system includes an e-mail sender 30 coupled to a WAN 32, and a wireless gateway 34, which provides an interface between the WAN 32 and a wireless network 36. A mobile device 38 is adapted to operate within the wireless network 36.

The e-mail sender 30 is a PC, such as the system 14 in FIG. 1, a network-connected computer, such as computer 28 in FIG. 1, or a mobile device, on which a messaging client operates to enable e-mail messages to be composed and sent. The WAN 32, wireless gateway 34, wireless network 36 and mobile device 38 are substantially the same as similarly-labelled components in FIG. 1.

In an example digital signature scheme, a secure e-mail message sender 30 digitally signs a message by taking a digest of the message and signing the digest using the sender's private key. A digest may, for example, be generated by performing a check-sum, a Cyclic Redundancy Check (CRC), a hash, or some other non-reversible operation on the message. This digest is then digitally signed by the sender using the sender's private key. The private key is used to perform an encryption or some other transformation operation on the digest to generate a digest signature. A digital signature, including the digest and the digest signature, is then appended to the outgoing message. In addition, a digital Certificate (Cert) of the sender, which includes the sender's public key and sender identity information that is bound to the public key with one or more digital signatures, and possibly any chained Certs and Certificate Revocation Lists (CRLs) associated with the Cert and any chained Certs, is often included with the outgoing message.

The secure e-mail message 40 sent by the e-mail sender 30 includes a component 42 including the sender's Cert, Cert

chain, CRLs and digital signature and the signed message body **44**. In the S/MIME secure messaging technique, Certs, CRLs and digital signatures are normally placed at the beginning of a message as shown in FIG. 2, and the message body is included in a file attachment. Messages generated by other secure messaging schemes may place message components in a different order than shown or include additional and/or different components. For example, a signed message **40** may include addressing information, such as "To:" and "From:" email addresses, and other header information not shown in FIG. 2.

When the secure e-mail message **40** is sent from the e-mail sender **30**, it is routed through the WAN **32** to the wireless gateway **34**, through the wireless network **36**, and then to the mobile device **38**. As described above, an e-mail message sender may alternatively send a message directly to a wireless gateway, to a computer system associated with a mobile device, or to a wireless VPN router or other interface for delivery to a mobile device.

The receiver of the signed message **40**, the mobile device **38**, typically verifies the digital signature **42** in the secure message **40** by generating a digest of the message body **44**, extracting the transmitted digest from the digital signature **42**, comparing the generated digest with the digest extracted from the digital signature **42**, and then verifying the digest signature in the digital signature. The digest algorithm used by a secure message receiver to generate the generated digest is the same as the algorithm used by the message sender, and is normally specified in a message header, or possibly in a digital signature of the secure message. Commonly used digest algorithm include the Secure Hash Algorithm 1 (SHA1) and Message-Digest Algorithm 5 (MD5), although other digest algorithms may be used.

It should be appreciated that the systems and methods described herein are in no way limited to the above, or any other digital signature scheme. The systems and methods described herein are substantially independent of the manner in which a key is to be used.

In order to verify the digest signature, the receiver **38** retrieves the public key of the sender **30**, generally by extracting the public key from the sender's Cert **42** attached to the message **40**, and then verifies the signature on the digest in the digital signature by performing a reverse transformation on the digest signature. For example, if the message sender **30** generated the digest signature by encrypting the digest using its private key, then a receiver **38** uses the sender's public key to decrypt the digest signature to recover the original digest. The secure message **40** shown in FIG. 2 includes the sender's Cert **42**, from which the sender's public key can be extracted. Where the sender's public key was extracted from an earlier message from the sender **30** and stored in a key store in the receiver's local store, the sender's public key may instead be retrieved from the local store. Alternatively, the public key may be retrieved from the sender's Cert stored in a local store, or from a Public Key Server (PKS). A PKS is a server that is normally associated with a Certificate Authority (CA) from which a Cert for an entity, including the entity's public key, is available. A PKS might reside within a corporate LAN such as **18** (FIG. 1), or anywhere on the WAN **32**, Internet or other network or system through which message receivers may establish communications with the PKS.

The Cert, Cert chain and CRLs **42** are used by a receiver to ensure that the sender's Cert is valid, i.e., that the Cert has not been revoked or expired, and is trusted. A Cert is often part of a Cert chain, which includes a user's Cert as well as other Certs to verify that the user's Cert is authentic. For example, a Cert for any particular entity typically includes the entity's

public key and identification information that is bound to the public key with a digital signature. Several types of Cert currently in use include, for example, X.509 Certs, which are typically used in S/MIME, and POP Certs, which have a slightly different format. The digital signature in a Cert is generated by the issuer of the Cert, and is checked by a message receiver as described above. A Cert may include an expiry time or validity period from which a messaging client determines if the Cert has expired. When a CRL is available, the Cert is checked against the CRL to ensure that the Cert has not been revoked.

If the digital signature in a message sender's Cert is verified, the Cert has not expired or been revoked, and the issuer of the Cert is trusted by a message receiver, then the digital signature of the message is trusted by the message receiver. If the issuer of the Cert is not trusted, then the message receiver traces a certification path through the Cert chain to verify that each Cert in the chain was signed by its issuer, whose Cert is next in the Cert chain, until a Cert is found that was signed by a root Cert from a trusted source, such as a large PKS. Once a root Cert is found, then a signature can be trusted, because both the sender and receiver trust the source of the root Cert.

If a secure message was encrypted or otherwise processed by a message sender after being signed, then each receiver first decrypts or performs other inverse processing operations on the message before signature verification is performed. Where encryption or other processing was performed before signing, however, inverse processing such as decryption is performed after signature verification. Encryption and decryption involve applying a cryptographic key and cipher algorithm to information to be encrypted or decrypted. Encryption and decryption use corresponding cipher algorithms, which may or may not be the same, and either the same or different cryptographic keys. In public key systems, different keys are used for encryption and decryption, whereas in "shared secret" type operations, the same key, a secret shared between a sender and recipient, is used for both encryption and decryption.

Access to a user's public key is also required when an outgoing message addressed to that user is to be encrypted according to a public key encryption algorithm. However, when an error is encountered during a public key access operation, known messaging clients provide little or no information as to the nature of any errors and possible solutions.

FIG. 3 is a block diagram of a wireless mobile communication device implementing a public key access scheme. The mobile device **38** includes a memory **52**, a messaging client **60**, a user interface (UI) **62**, a display **63**, and a wireless transceiver **64**.

The memory **52** is a writeable store such as a RAM into which other device components and systems write data, and includes a storage area for a Cert store **54**, an address book **56** in which messaging contact information is stored, and an application data storage area **58** which stores data associated with software applications on the mobile device **38**. Data stores **54**, **56**, and **58** are illustrative examples of stores that may be implemented in a memory **52** on mobile device **38**. The memory **52** is also typically used by other device systems in addition to those shown in FIG. 3 to store other types of data.

The messaging system **60** is connected to the wireless transceiver **64** and is thus enabled for communications via a wireless network.

The UI **62** may include such UI components as a keyboard or keypad, or other components which accept inputs from or provide outputs to a user of the mobile device **38**. A mobile

device **38** will typically include more than one UI, and the UI **62** therefore represents one or more user interfaces.

In the mobile device **38**, the display **63** is typically a liquid crystal display (LCD), although other types of display may instead be used in mobile devices. The display **63** is also a user interface, but is shown separately in FIG. **3**.

The messaging client **60** stores received Certs to the Cert store **54** and retrieves stored Certs from the Cert store **54**. Certs are normally stored in the Cert store **54** in the format in which they are received, but may alternatively be parsed or otherwise translated into a storage format before being written to the Cert store **54**. Certs may be received with secure messages, requested from a Cert source such as a PKS via the wireless transceiver **64**, or loaded onto the mobile device **38** through a communications interface such as a serial port, Universal Serial Bus (USB) port, Infrared Data Association (IrDA) port, or Bluetooth™ module, from a similarly equipped external system, a PC for example. As described above, a public key in a Cert may be required for sending or receiving secure messages. Those skilled in the art will appreciate that a mobile device enabled for secure communications may include a separate key store for storing cryptographic keys, instead of or in addition to a Cert store **54**.

As described above, known messaging clients do not handle public key access problems well, typically indicating only that such a problem has occurred, thus leaving a user uninformed about the nature of the problem and/or any steps that could be taken to resolve the problem.

To address this and other aspects, the messaging client **60** may determine whether any problems with public key access have been encountered when a message is to be sent, and if so, what the problems are. The user is then allowed to attempt to resolve these problems before sending the message.

When a user composes an outgoing message and chooses to encrypt the message using each recipient's public key, using S/MIME, PGP or another secure messaging scheme, the messaging client **60** makes a list of all of the recipients for the outgoing message and collates all of the corresponding Certs, and then performs a series of checks on the Certs. Certs represent one possible format or mechanism for accessing public keys, and that the system in this example is in no way limited to Cert-based public key access.

A determination is made as to whether a Cert for each recipient is locally available to the messaging client **60**, by searching the Cert store **54**, for example. If it is not available, the messaging client **60** may invoke an LDAP (Lightweight Directory Access Protocol) or other type of search to find a Cert for the recipient. If a Cert is found, then the messaging client **60** can check the Cert. If no Cert is found, however, the user is preferably given the option to remove the recipient from the send list or to cancel the send operation for the composed message. The messaging client **60** may also check to see if the user is allowed to use each Cert for the purpose of encryption. This is determined, for example, based on a "Usage" field for the Cert (e.g., it may only be allowed to be used for signing, thereby prohibiting the mobile device from using it for encryption purpose; etc.) or a control file installed on the device **38** that specifies which Certs the user is allowed to use.

The messaging client **60** then preferably checks the "strength" of the certificate, defined by the size of the public key in the Curt, which is compared to a predefined setting stored at the mobile device **38**, such as in the above-mentioned control file. If the Cert, or the public key in particular, is not "strong" enough, then the user can either remove the recipient or cancel the operation. Where a control file has been installed on the mobile device **38**, this option can be

prevented by a setting that disallows Certs from being used that have been designated as "weak" by the control file.

A trust check, described above, may also be performed by the messaging client **60**. If the Cert is trusted, then it is used. Otherwise the user is asked if they wish to proceed, such as by removing the recipient from the message or cancelling the operation. Where a control file has been installed on the mobile device **38**, this option can be prevented by a setting that disallows untrusted Certs from being used.

Validity and revocation status of each Curt may also be determined. If the Curt validity dates have passed or the Cert has been revoked, then the user is alerted and asked if they wish to proceed. As described above for untrusted Certs, a control file or control settings on the mobile device **38** may be used to prevent a user from using invalid or revoked Certs. Thus, if any public key access problems occur, the user is alerted with what the problem is and how to resolve it.

FIGS. **4A-4C** illustrate an operational scenario example wherein a composed message is to be encrypted using a secure email encoding and sent. In order to encrypt the email for a particular recipient, an email system or software application obtains access to the public key associated with that recipient. Although this example describes the situation wherein the public key is contained in a digital certificate, it should be understood that depending on the particular secure email encoding that is being used, this public key may be contained inside a Cert or inside some other key container, and can be independent of the type of key container used by the secure email encoding. For example, although POP keys have many of the same properties as Certs, they are not usually referred to as Certs.

In step **70**, a list of all Certs associated with one intended recipient of the composed message is compiled. This list of Certs may be compiled by searching through a database of Certs stored in or accessed by the email system, for example. In step **72**, it is determined whether more than one Cert has been found for the recipient. If so, the list is trimmed in step **74** to include only those Certs that are "allowed" in the user's operating environment.

The determination of whether a Cert is allowed can be made in a number of ways. As an illustration, an IT or security administrator has the ability to send a set of certificate policies to the email system. These certificate policies can include a number of properties that certificates must have in order to be considered "allowed". By way of example, a certificate policy could specify that a certificate is allowed only if it has not expired, meaning that a user should not be permitted to use an expired certificate. Other examples of certificate policies could specify that a certificate is allowed only if it has not been revoked, if it is trusted (where the notion of trust is determined according to the model implied by the particular secure email encoding and type of key container), and/or if it contains a strong public key (where the notion of strength is determined by limits appropriate to current technology, or preferably by a set of key strength policies set by the administrator). There are many other certificate policies that could be set by the administrator, or potentially by a user.

In step **76**, it is determined whether there are any Certs remaining in the list of Certs for the recipient. If not, then the user is warned that there are no available allowed Certs, at step **78**. The warning presented to the user may give the user several different options. For example, the user may be able to remove the recipient from the list of intended recipients of the message, the user may be able to open a Cert search application, such as an LDAP browser, in order to fetch Certs for the recipient, the user may be able to manually select Certs to use for the recipient from a list of all allowed Certs in the system,

or the user may be able to send the message without encryption, thereby removing the need to obtain the recipient's Cert. Other options may be used. If the message send operation is aborted, then the message is not sent, as shown at **80**.

In step **82**, it is determined whether there is still more than one Cert in the list of Certs for the recipient. If this is the case, then all of the Certs in the list are allowed in the user's operating environment, because the list was trimmed in step **74**. At this point, a dialog is displayed at step **84** which asks the user to select one or more Certs to use from the list of available Certs. After the user has selected a set of Certs, it is determined at step **86** whether all of the selected Certs are recommended. The determination of whether a Cert is recommended can be made in a number of ways. As an illustration, a Cert is recommended if it has not been revoked, if it is trusted, if it has not expired, and/or if it contains a strong public key, although there are other criteria that could be considered. It should be noted that a Cert that is not recommended may still be allowed, such as depending on the set of certificate policies set by the administrator.

If one or more of the selected certificates is not recommended, then in step **88** the user is warned. If the user chooses to continue at step **96**, then the message is encrypted to the recipient using the public keys found in that set of Certs and sent at step **94**. If the user chooses not to continue, processing returns to the dialog at step **84** and the user is asked to revise the Cert selection.

If the method reaches step **90**, then there was exactly one Cert found for the recipient. If that single Cert is not allowed in the user's operating environment, then the user will be warned at step **92**. This warning preferably contains a specific description of the reason or reasons that the Cert was not allowed. It is to be understood that the information about this warning could be saved in a temporary location until all of the recipients of the message have been processed, at which point a set of combined warnings for all of the intended recipients could be displayed. This warning, like the warning in step **78**, presents the user with a similar set of options to allow the user to recover from this situation.

If the single certificate is allowed, in step **98** it is determined whether the Cert is recommended. If it is not recommended, the user will be warned at step **100**. Again, this warning preferably contains a specific description of the reason or reasons that the certificate was not recommended. As above, the information about this warning could be saved in a temporary location until all of the recipients of the message have been processed, at which point a set of combined warnings for all of the intended recipients could be displayed. This warning, like the previously described warnings, presents the user with a similar set of options to allow the user to recover from this situation. In addition, the user is allowed to continue using the Cert at step **102**, since in this case even though the certificate is not recommended for use, it is allowed. The message is then either encrypted and sent at step **104** or not sent, as indicated at **106**.

The message is also encrypted and sent at step **104** if it is determined at step **98** that the single Cert is recommended. The steps shown in FIGS. **4A-4C** may be repeated for each intended recipient of a composed message before sending the message.

FIGS. **4A-4C** show an operational scenario of a public key access method. It should be apparent that operations and methods described herein may include further, fewer or different steps than those shown in FIGS. **4A-4C**. For example, a method need not perform every check shown in FIGS. **4A-4C**, and checks may be performed in a different order than shown in FIGS. **4A-4C**. As another example, if a user is

warned that a Cert is not available (such as at step **78**, step **92**, or step **100**), then the user can be presented with an option to use LDAP services to locate another Cert for a recipient.

In addition, instructions (e.g., software-based, firmware-based, etc.) that can operate on a mobile device's processor may implement the operations disclosed herein. The instructions may be implemented as a secure message processing module, which may have one or more modules to retrieve the data needed to perform the checking as well as one or more modules to perform the checks and to act based upon the results of the checking. The instructions may be separate to or a part of the messaging client **60** and utilize data structures as part of its operations, such as to store results from the checking-related operations. Among other things, the instructions provide information on the nature of the error and/or possible corrective actions. Also, when an error occurs, a user may still be allowed to send the message, such as by allowing the user to proceed after be appraised of the warnings associated with a recipient. Still further, data signals transmitted via a communication channel may be used with the systems and methods. The data signals can include any type of data or voice information, such as an encoded message transmitted to and/or from a mobile device. The data signal may be packetized data that is transmitted through a carrier wave or other medium across the network. Still further computer-readable media may be provided to and used with the mobile device for causing a mobile device to perform the methods and implement the systems disclosed herein.

The methods and systems may be used with a wide assortment of electronic devices, such as a personal digital assistant (PDA) device or the mobile device **600** shown in FIG. **5**. With reference to FIG. **5**, the mobile device **600** is preferably a two-way communication device having at least voice and data communication capabilities. The mobile device **600** preferably has the capability to communicate with other computer systems on the Internet. Depending on the functionality provided by the device, the device may be referred to as a data messaging device, a two-way pager, a cellular telephone with data messaging capabilities, a wireless Internet appliance or a data communication device (with or without telephony capabilities).

The mobile device **600** includes a transceiver **611**, a microprocessor **638**, a display **622**, non-volatile memory **624**, RAM **626**, auxiliary input/output (I/O) devices **628**, a serial port **630**, a keyboard **632**, a speaker **634**, a microphone **636**, a short-range wireless communications sub-system **640**, and other device sub-systems **642**. The transceiver **611** includes transmit and receive antennas **616**, **618**, a receiver (Rx) **612**, a transmitter (Tx) **614**, one or more local oscillators (LOs) **613**, and a digital signal processor (DSP) **620**. Within the non-volatile memory **624**, the mobile device **600** includes a plurality of software modules **624A-624N** that can be executed by the microprocessor **638** (and/or the DSP **620**), including a voice communication module **624A**, a data communication module **624B**, and a plurality of other operational modules **624N** for carrying out a plurality of other functions.

As described above, the mobile device **600** is preferably a two-way communication device having voice and data communication capabilities. Thus, for example, the mobile device **600** may communicate over a voice network, such as any of the analog or digital cellular networks, and may also communicate over a data network. The voice and data networks are depicted in FIG. **5** by the communication tower **619**. These voice and data networks may be separate communication networks using separate infrastructure, such as base stations, network controllers, etc., or they may be integrated into a single wireless network.

11

The communication subsystem **611** is used to communicate with the network **619**. The DSP **620** is used to send and receive communication signals to and from the transmitter **614** and receiver **612**, and may also exchange control information with the transmitter **614** and receiver **612**. If the voice and data communications occur at a single frequency, or closely-spaced set of frequencies, then a single LO **613** may be used in conjunction with the transmitter **614** and receiver **612**. Alternatively, if different frequencies are utilized for voice communications versus data communications, then a plurality of LOs **613** can be used to generate a plurality of frequencies corresponding to the network **619**. Although two antennas **616**, **618** are depicted in FIG. 5, the mobile device **600** could be used with a single antenna structure. Information, which includes both voice and data information, is communicated to and from the communication module **611** via a link between the DSP **620** and the microprocessor **638**.

The detailed design of the communication subsystem **611**, such as frequency band, component selection, power level, etc., will be dependent upon the communication network **619** in which the mobile device **600** is intended to operate. For example, a mobile device **600** intended to operate in a North American market may include a communication subsystem **611** designed to operate with the Mobitex or DataTAC mobile data communication networks and also designed to operate with any of a variety of voice communication networks, such as AMPS, TDMA, CDMA, PCS, etc., whereas a mobile device **600** intended for use in Europe may be configured to operate with the GPRS data communication network and the GSM voice communication network. Other types of data and voice networks, both separate and integrated, may also be utilized with the mobile device **600**.

Depending upon the type of network **619**, the access requirements for the dual-mode mobile device **600** may also vary. For example, in the Mobitex and DataTAC data networks, mobile devices are registered on the network using a unique identification number associated with each device. In GPRS data networks, however, network access is associated with a subscriber or user of a mobile device **600**. A GPRS device typically requires a subscriber identity module ("SIM"), which is required in order to operate the mobile device **600** on a GPRS network. Local or non-network communication functions (if any) may be operable, without the SIM, but the mobile device **600** will be unable to carry out any functions involving communications over the network **619**, other than any legally required operations, such as '911' emergency calling.

After any required network registration or activation procedures have been completed, the mobile device **600** may send and receive communication signals, preferably including both voice and data signals, over the network **619**. Signals received by the antenna **616** from the communication network **619** are routed to the receiver **612**, which provides for signal amplification, frequency down conversion, filtering, channel selection, etc., and may also provide analog to digital conversion. Analog to digital conversion of the received signal allows more complex communication functions, such as digital demodulation and decoding to be performed using the DSP **620**. In a similar manner, signals to be transmitted to the network **619** are processed, including modulation and encoding, for example, by the DSP **620** and are then provided to the transmitter **614** for digital to analog conversion, frequency up conversion, filtering, amplification and transmission to the communication network **619** via the antenna **618**. Although a single transceiver **611** is shown in FIG. 5 for both voice and data communications, the mobile device **600** may include two distinct transceivers, a first transceiver for transmitting and

12

receiving voice signals, and a second transceiver for transmitting and receiving data signals.

In addition to processing the communication signals, the DSP **620** also provides for receiver and transmitter control. For example, the gain levels applied to communication signals in the receiver **612** and transmitter **614** may be adaptively controlled through automatic gain control algorithms implemented in the DSP **620**. Other transceiver control algorithms could also be implemented in the DSP **620** in order to provide more sophisticated control of the transceiver **611**.

The microprocessor **638** preferably manages and controls the overall operation of the mobile device **600**. Many types of microprocessors or microcontrollers could be used for this part, or, alternatively, a single DSP **620** could be used to carry out the functions of the microprocessor **638**. Low-level communication functions, including at least data and voice communications, are performed through the DSP **620** in the transceiver **611**. Other, high-level communication applications, such as a voice communication application **624A**, and a data communication application **624B** may be stored in the non-volatile memory **624** for execution by the microprocessor **638**. For example, the voice communication module **624A** may provide a high-level user interface operable to transmit and receive voice calls between the mobile device **600** and a plurality of other voice devices via the network **619**. Similarly, the data communication module **624B** may provide a high-level user interface operable for sending and receiving data, such as e-mail messages, files, organizer information, short text messages, etc., between the mobile device **600** and a plurality of other data devices via the network **619**.

The microprocessor **638** also interacts with other device subsystems, such as the display **622**, non-volatile memory **624**, random access memory (RAM) **626**, auxiliary input/output (I/O) subsystems **628**, serial port **630**, keyboard **632**, speaker **634**, microphone **636**, a short-range communications subsystem **640** and any other device subsystems generally designated as **642**. The components **628**, **632**, **634** and **636** are examples of the types of subsystems that could be provided as UIs **62** (FIG. 3). The modules **624A-N** are executed by the microprocessor **638** and may provide a high-level interface between a user of the mobile device and the mobile device. This interface typically includes a graphical component provided through the display **622**, and an input/output component provided through the auxiliary I/O **628**, keyboard **632**, speaker **634**, or microphone **636**.

Some of the subsystems shown in FIG. 5 perform communication-related functions, whereas other subsystems may provide "resident" or on-device functions. Notably, some subsystems, such as keyboard **632** and display **622** may be used for both communication-related functions, such as entering a text message for transmission over a data communication network, and device-resident functions such as a calculator or task list or other PDA type functions.

Operating system software used by the microprocessor **638** is preferably stored in a persistent store such as non-volatile memory **624**. In addition to the operating system and communication modules **624A-N**, the non-volatile memory **624** may also include a file system for storing data. A storage area is also preferably provided in the non-volatile memory **624** to store public keys, a private key, and other information required for secure messaging. The operating system, specific device applications or modules, or parts thereof, may be temporarily loaded into a volatile store, such as RAM **626** for faster operation. Moreover, received communication signals may also be temporarily stored to RAM **626** before permanently writing them to a file system located in the non-volatile store **624**. As those skilled in the art will appreciate, the

13

non-volatile store **624** may be implemented as a Flash memory component or a battery backed-up RAM, for example.

An exemplary application module **624N** that may be loaded onto the mobile device **600** is a personal information manager (PIM) application providing PDA functionality, such as calendar events, appointments, and task items. This module **624N** may also interact with the voice communication module **624A** for managing phone calls, voice mails, etc., and may also interact with the data communication module **624B** for managing e-mail communications and other data transmissions. Alternatively, all of the functionality of the voice communication module **624A** and the data communication module **624B** may be integrated into the PIM module.

The non-volatile memory **624** preferably provides a file system to facilitate storage of PIM data items on the device. The PIM application preferably includes the ability to send and receive data items, either by itself, or in conjunction with the voice and data communication modules **624A**, **624B**, via the wireless network **619**. The PIM data items are preferably seamlessly integrated, synchronized and updated, via the wireless network **619**, with a corresponding set of data items stored or associated with a host computer system, thereby creating a mirrored system for data items associated with a particular user.

The mobile device **600** may also be manually synchronized with a host system by placing the mobile device **600** in an interface cradle, which couples the serial port **630** of the mobile device **600** to the serial port of the host system. The serial port **630** may also be used to download other application modules **624N** for installation, and to load Certs, keys and other information onto a device. This wired download path may be used to load an encryption key onto the mobile device **600**, which is a more secure method than exchanging encryption information via the wireless network **619**.

Additional application modules **624N** may be loaded onto the mobile device **600** through the network **619**, through an auxiliary I/O subsystem **628**, through the serial port **630**, through the short-range communications subsystem **640**, or through any other suitable subsystem **642**, and installed by a user in the non-volatile memory **624** or RAM **626**. Such flexibility in application installation increases the functionality of the mobile device **600** and may provide enhanced on-device functions, communication-related functions, or both. For example, secure communication applications may enable electronic commerce functions and other such financial transactions to be performed using the mobile device **600**.

When the mobile device **600** is operating in a data communication mode, a received signal, such as a text message or a web page download, is processed by the transceiver **611** and provided to the microprocessor **638**, which preferably further processes the received signal for output to the display **622**, or, alternatively, to an auxiliary I/O device **628**. A user of mobile device **600** may also compose data items, such as email messages, using the keyboard **632**, which is preferably a complete alphanumeric keyboard laid out in the QWERTY style, although other styles of complete alphanumeric keyboards such as the known DVORAK style may also be used. User input to the mobile device **600** is further enhanced with a plurality of auxiliary I/O devices **628**, which may include a thumbwheel input device, a touchpad, a variety of switches, a rocker input switch, etc. The composed data items input by the user may then be transmitted over the communication network **619** via the transceiver **611**.

When the mobile device **600** is operating in a voice communication mode, the overall operation of the mobile device **600** is substantially similar to the data mode, except that

14

received signals are preferably output to the speaker **634** and voice signals for transmission are generated by a microphone **636**. Alternative voice or audio I/O subsystems, such as a voice message recording subsystem, may also be implemented on the mobile device **600**. Although voice or audio signal output is preferably accomplished primarily through the speaker **634**, the display **622** may also be used to provide an indication of the identity of a calling party, the duration of a voice call, or other voice call related information. For example, the microprocessor **638**, in conjunction with the voice communication module **624A** and the operating system software, may detect the caller identification information of an incoming voice call and display it on the display **622**.

A short-range communications subsystem **640** is also included in the mobile device **600**. For example, the subsystem **640** may include an infrared device and associated circuits and components, or a short-range wireless communication module such as a Bluetooth™ communication module or an 802.11 module to provide for communication with similarly-enabled systems and devices. Those skilled in the art will appreciate that “Bluetooth” and “802.11” refer to sets of specifications, available from the Institute of Electrical and Electronics Engineers (IEEE), relating to wireless personal area networks and wireless LANs, respectively.

It will be appreciated that the above description relates to preferred embodiments by way of example only. Many variations on the systems and methods described above will occur to those knowledgeable in the field, and such variations are within the scope of the invention as claimed, whether or not expressly described.

For example, although a wireless mobile communication device is shown in FIG. 5 and described as one possible system on which a messaging client may operate, public key access systems and methods may also be implemented in other messaging clients, including those configured for operation on desktop, laptop, or networked computer systems.

It is claimed:

1. A method for handling on an electronic device a secure message to be sent from the electronic device to an intended recipient, the method comprising:

receiving data at the electronic device about at least one of a security key or certificate associated with the intended recipient;

using the received data to perform a check with respect to using the at least one of the security key or certificate associated with the intended recipient to send the secure message to the intended recipient, wherein the performed check determines whether at least one certificate or security key for the intended recipient can be located, wherein an issue exists due to the check; and

providing, via a user interface on the electronic device, information describing the issue and at least one potential action for resolving the issue, wherein the information describing the issue that is provided includes that the intended recipient's certificate or security key was not located, wherein the at least one potential action for resolving the issue comprises one or more of the following: (i) opening a certificate search application to identify a certificate for the intended recipient, or (ii) manually selecting a certificate to use for the intended recipient from a list of all allowed certificates.

2. The method of claim 1, wherein the at least one potential action for resolving the issue includes identifying a locally available certificate or security key for the intended recipient on the electronic device.

15

3. The method of claim 1, wherein the at least one potential action for resolving the issue includes identifying a remotely available certificate or security key for the intended recipient.

4. The method of claim 1, further comprising resolving the issue associated with using the at least one of the security key or certificate through use of the information provided and user input received via the user interface.

5. The method of claim 1, further comprising sending the secure message to the intended recipient after resolution of the issue.

6. The method of claim 1, further comprising removing the intended recipient whose certificate or security key was not located before sending the secure message to another recipient.

7. A non-transitory, computer-readable storage medium comprising instructions executable by a processor in an electronic device that upon execution cause the electronic device to be operable to:

receive data at the electronic device about at least one of a security key or certificate associated with an intended recipient;

use the received data to perform a check with respect to using the at least one of the security key or certificate associated with the intended recipient to send a secure message to the intended recipient, wherein the performed check determines whether at least one certificate or security key for the intended recipient can be located, wherein an issue exists due to the check; and

provide, via a user interface on the electronic device, information describing the issue and at least one potential action for resolving the issue, wherein the information describing the issue that is provided includes that the intended recipient's certificate or security key was not located, wherein the at least one potential action for resolving the issue comprises one or more of the following: (i) opening a certificate search application to identify a certificate for the intended recipient, or (ii) manually selecting a certificate to use for the intended recipient from a list of all allowed certificates.

8. The medium of claim 7, wherein the at least one potential action for resolving the issue includes identifying a locally available certificate or security key for the intended recipient on the electronic device.

9. The medium of claim 7, wherein the at least one potential action for resolving the issue includes identifying a remotely available certificate or security key for the intended recipient.

10. The medium of claim 7, the instructions further operable to resolve the issue associated with using the at least one of the security key or certificate through use of the information provided and user input received via the user interface.

11. The medium of claim 7, the instructions further operable to send the secure message to the intended recipient after resolution of the issue.

16

12. The medium of claim 7, the instructions further operable to remove the intended recipient whose certificate or security key was not located before sending the secure message to another recipient.

13. An apparatus for handling on an electronic device a secure message to be sent from the electronic device to an intended recipient, the apparatus comprising:

a secure message processing module for use with a messaging client that sends electronic messages;

wherein the secure message processing module receives data about at least one of a security key or certificate associated with the recipient;

wherein the secure message processing module uses the received data to perform a check with respect to using the at least one of the security key or certificate associated with the intended recipient to send the secure message to the intended recipient, wherein the performed check determines whether at least one certificate or security key for the intended recipient can be located, wherein an issue exists due to the check; and

wherein the secure message processing module is configured to provide, via a user interface, information describing the issue and at least one potential action for resolving the issue, wherein the information describing the issue that is provided includes that the intended recipient's certificate or security key was not located, wherein the at least one potential action for resolving the issue comprises removing the intended recipient whose certificate or security key was not located before sending the secure message to another recipient one or more of the following: (i) opening a certificate search application to identify a certificate for the intended recipient, or (ii) manually selecting a certificate to use for the intended recipient from a list of all allowed certificates.

14. The apparatus of claim 13, wherein the at least one potential action for resolving the issue includes identifying a locally available certificate or security key for the intended recipient on the electronic device.

15. The apparatus of claim 13, wherein the at least one potential action for resolving the issue includes identifying a remotely available certificate or security key for the intended recipient.

16. The apparatus of claim 13, the secure message processing module further configured to resolve the issue associated with using the at least one of the security key or certificate through use of the information provided and user input received via the user interface.

17. The apparatus of claim 13, the secure message processing module further configured to send the secure message to the intended recipient after resolution of the issue.

18. The apparatus of claim 13, the secure message processing module further configured to remove the intended recipient whose certificate or security key was not located before sending the secure message to another recipient.
